

# Matrix Decomposition with Kronecker Weights

Jan de Leeuw

April 23, 2026

The familiar orthogonal decomposition of a matrix into row effect, column effects, and interactions is generalized to a matrix space with the Kronecker inner product.

# 1 Kronecker Weights

$R$  and  $C$  are positive semidefinite matrices of order  $n$  and  $m$ . They define an inner product on the space  $\mathbb{R}^{n \times m}$  of  $n \times m$  matrices as  $\langle X, Y \rangle_{RC} = \text{tr } RXC Y'$  and a corresponding squared norm (pseudo-norm if either  $R$  or  $C$  is singular) as  $\|X\|_{RC}^2 = \langle X, X \rangle_{RC}$ . From now on we leave out the subscript  $RC$ .

## 2 Matrix Decomposition

Define three subspaces of  $\mathbb{R}^{n \times m}$ . We use  $e$  for vectors with all elements equal to one. The number of elements in  $e$  will be clear from the context, otherwise we will use  $e_m$  and  $e_n$ .

1.  $\mathbb{L}_\mu$ , constant matrices,  $X = \mu e_n e'_m$ .
2.  $\mathbb{L}_a$ , matrices with all columns the same,  $X = a e'_m$ .
3.  $\mathbb{L}_b$ , matrices with all rows the same  $X = e_n b'$ .

We will choose  $a, b, \mu$  such that these three subspaces are orthogonal in the Kronecker inner product. For this we need

$$\text{tr } R\mu e e' C e a' = \mu a' R e \times e' C e = 0, \quad (1a)$$

$$\text{tr } R\mu e e' C b e' = \mu b' C e \times e' R e, \quad (1b)$$

$$\text{tr } R a e' C b e' = a' R e \times b' C e. \quad (1c)$$

It follows the three subspaces are orthogonal if  $a' R e = b' C e = 0$ . Thus we redefine our subspaces as

1.  $\mathbb{L}_\mu$ : all  $X$  with  $X = \mu e e'$ .
2.  $\mathbb{L}_a$ : all  $X$  with  $X = a e'$  where  $a' R e = 0$ .
3.  $\mathbb{L}_b$ : all  $X$  with  $X = e b'$  where  $b' C e = 0$ .

Now project, in the Kronecker metric, matrix  $X$  on each of these orthogonal subspaces.

First on  $\mathbb{L}_\mu$ . Minimize over  $\mu$

$$\|X - \mu e e'\|^2 = \|X\|^2 - 2\mu e' R X C e + \mu^2 e' R e \times e' C e, \quad (2)$$

and thus

$$\hat{\mu} = \frac{e' R X C e}{e' R e \times e' C e}. \quad (3)$$

Now over  $\mathbb{L}_a$ . We have

$$\|X - ae'\|^2 = \|X\|^2 - 2a'RXCe + a'Ra \times e'Ce, \quad (4)$$

which must be minimized over all  $a'Re = 0$ . Use a Lagrange multiplier  $\lambda$ . Stationary equations are

$$RXCe - \lambda Re = e'Ce \times Ra. \quad (5)$$

Premultiply by  $e'$  gives

$$\hat{\lambda} = \frac{e'RXCe}{e'Re}, \quad (6)$$

and thus

$$e'Ce \times \hat{a} = XCe - e \frac{e'RXCe}{e'Re}, \quad (7)$$

or

$$\hat{a} = \left( I - \frac{ee'R}{e'Re} \right) X \left( \frac{Ce}{e'Ce} \right). \quad (8)$$

It is convenient to define the projectors

$$P := \frac{ee'R}{e'Re}, \quad (9)$$

$$Q := \frac{Cee'}{e'Ce}. \quad (10)$$

The projection on  $\mathbb{L}_a$  is

$$\hat{a}e' = (I - P)XQ. \quad (11)$$

Projecting on  $\mathbb{L}_b$  is similar, by symmetry. Thus

$$e\hat{b}' = PX(I - Q). \quad (12)$$

In addition, from (3),

$$\hat{\mu}ee' = PXQ. \quad (13)$$

It follows that if we define

$$\hat{H} := X - \hat{\mu}ee' - \hat{a}e' - e\hat{b}' \quad (14)$$

then

$$\hat{H} = (I - P)X(I - Q). \quad (15)$$

Define  $\mathbb{L}_h$  as the subspace of all matrices of this form, or equivalently the matrices with  $HCe = 0$  and  $e'RH = 0$ .

Because  $(I - Q)Ce = 0$  it follows that

$$\text{tr } R\hat{H}C(\hat{\mu}ee') = 0 \quad (16a)$$

and

$$\text{tr } R\hat{H}C(\hat{e}b') = 0 \quad (16b)$$

and

$$\text{tr } R\hat{a}e'CH' = 0 \quad (16c)$$

Thus  $\mathbb{L}_h$  is also orthogonal in the Kronecker inner product to the other three subspaces. It follows that in the Kronecker norm

$$\|X\|^2 = \|PXQ\|^2 + \|(I - P)XQ\|^2 + \|PX(I - Q)\|^2 + \|(I - P)X(I - Q)\|^2, \quad (17)$$

and thus we not only have a decomposition of the data  $X$ , but also of its Kronecker sum of squares.

It also follows that if  $Y = \mu ee' + ae' + eb' + H$ , with  $a'Re = b'Ce = 0$ , then

$$\begin{aligned} \|X - Y\|^2 = & \|PXQ - \mu ee'\|^2 + \|(I - P)XQ - ae'\|^2 + \\ & \|PX(I - Q) - eb'\|^2 + \|(I - P)X(I - Q) - H\|^2 \end{aligned} \quad (18)$$

Thus if we are fitting  $Y$  to  $X$  with seperable restrictions on  $a$ ,  $b$ , and  $H$  (in addition to  $a'Re = b'Ce = 0$ ) then we can minimize each of the four components separately.

We have defined  $H$  in (14) as the residual after projecting on the three orthogonal spaces. The orthogonality of the residual space is YAPT (Yet Another Pythagorean Theorem). Alternatively, we could have defined  $\mathbb{L}_h$  as the space of  $n \times m$  matrices satisfying  $HCe = 0$  and  $H'Re = 0$  and project on this space. This will produce the same  $\hat{H}$ .

The developments in this paper can be generalized in several ways. In the first place the same reasoning applies to multiway arrays. If the array has  $p$  “dimensions” then there are  $2^p$  components. Secondly, vectors  $e_n$  and  $e_m$  in the formulas can be replaced by any vectors  $u$  and  $v$  with  $n$  and  $m$  elements. In fact, with some additional notation, they can be replaced by matrices  $U$  and  $V$ . And finally the results apply to any finite sequence of orthogonal subspaces in any (finite-dimensional) inner product space.

### 3 Example

```
set.seed(12345)
ymat <- matrix(rnorm(12), 4, 3)
rmat <- crossprod(matrix(rnorm(40), 10, 4)) / 10
cmat <- crossprod(matrix(rnorm(30), 10, 3)) / 10
```

[1] "ymat"

```
      [,1]      [,2]      [,3]
[1,] 0.5855288 0.6058875 -0.2841597
[2,] 0.7094660 -1.8179560 -0.9193220
[3,] -0.1093033 0.6300986 -0.1162478
[4,] -0.4534972 -0.2761841 1.8173120
```

[1] "cmat"

```
      [,1]      [,2]      [,3]
[1,] 1.3744581 0.7610956 -0.2692483
[2,] 0.7610956 1.2428719 -0.1845269
[3,] -0.2692483 -0.1845269 1.3504256
```

[1] "rmat"

```
      [,1]      [,2]      [,3]      [,4]
[1,] 0.6606540 0.6316750 0.2060831 0.4388240
[2,] 0.6316750 1.5141559 -0.7485539 0.5940988
[3,] 0.2060831 -0.7485539 2.0102613 -0.4442019
[4,] 0.4388240 0.5940988 -0.4442019 1.3318363
```

We now apply the `decompose()` function from the code section.

```
h<-decompose(yamat, rmat, cmat)
```

The four components are:

```
[[1]]
      [,1]      [,2]      [,3]
[1,] -0.01383449 -0.01383449 -0.01383449

[4,]	2.081668e-17	-5.551115e-17	-8.604228e-16	9.280312e+00

The trace of the inner product matrix and the squared norm of the data:

[1] 12.88097 12.88097

## 4 Code

```
set.seed(12345)
ymat <- matrix(rnorm(12), 4, 3)
rmat <- crossprod(matrix(rnorm(40), 10, 4)) / 10
cmat <- crossprod(matrix(rnorm(30), 10, 3)) / 10

decompose <- function(xmat, rmat, cmat) {
  n <- nrow(xmat)
  m <- ncol(xmat)
  pmat <- matrix(colSums(rmat), n, n, byrow = TRUE) / sum(rmat)
  qmat <- matrix(rowSums(cmat), m, m) / sum(cmat)
  px <- pmat %*% xmat
  xq <- xmat %*% qmat
  dd <- rep(list(0), 4)
  dd[[1]] <- px %*% qmat
  dd[[2]] <- px - dd[[1]]
  dd[[3]] <- xq - dd[[1]]
  dd[[4]] <- xmat - dd[[1]] - dd[[2]] - dd[[3]]
  ip <- matrix(0, 4, 4)
  for (i in 1:4) {
    for (j in 1:4) {
      ip[i, j] <- kroneckerIP(dd[[i]], dd[[j]], rmat, cmat)
    }
  }
  ssq <- c(kroneckerIP(xmat, xmat, rmat, cmat), sum(diag(ip)))
  return(list(dd = dd, ip = ip, ssq = ssq))
}

kroneckerIP <- function(xmat, ymat, rmat, cmat) {
  return(sum(ymat * (rmat %*% xmat %*% cmat)))
}
```
